## ***About this Guide***

---

The *MediaFS Developer's Guide* presents how the media filesystem (MediaFS) module expects device drivers to describe media devices and mediastores, and the *devctl()* messages that these drivers need to support.

This *Guide* is intended for:

- developers who design and write device drivers for use with MediaFS
- developers who integrate support for these devices into higher-level applications that use the MediaFS interface — applications such as the QNX<sup>®</sup> Aviage Multimedia Suite's Multimedia Engine (MME)

For more information about the MME, see *Introduction to the MME* and the other books in the MME documentation set.

The table below may help you find what you need in this book:

<b>For information about:</b>	<b>See:</b>
The MediaFS standardized interface	MediaFS Overview
The structure of MediaFS, and required POSIX function support	MediaFS Structure
MediaFS entities, including files, directories and symbolic links	MediaFS Entities
Media changer presentation to MediaFS	Media Changers
How to present playback states and controls to MediaFS	Managing Playback

Playback structures and constants used by MediaFS	Playback Structures and Constants
How to retrieve album art	Getting Album Art
MediaFS events and their structures	MediaFS Events
Examples of code used to work with MediaFS	Appendix A: Examples

Other MME documentation available to application developers includes:

<b>Book</b>	<b>Description</b>
<i>Introduction to the MME</i>	MME Architecture, Quickstart Guide, and FAQs.
<i>MME Developer's Guide</i>	How to use the MME to program client applications.
<i>MME API Library Reference</i>	MME API functions, data structures, enumerated types, and events.
<i>MME Technotes</i>	MME technical notes.
<i>MME Utilities</i>	Utilities used by the MME.
<i>MME Configuration Guide</i>	How to configure the MME.
<i>QDB Developer's Guide</i>	QDB database engine programming guide and API library reference.

Note that the MME is a component of the QNX Aviage multimedia core package, which is available in the QNX Aviage multimedia suite of products. The MME is the main component of this core package. It is used for configuration and control of your multimedia applications.

## Typographical conventions

Throughout this manual, we use certain typographical conventions to distinguish technical terms. In general, the conventions we use conform to those found in IEEE POSIX publications. The following table summarizes our conventions:

<b>Reference</b>	<b>Example</b>
Code examples	<code>if( stream == NULL )</code>
Command options	<code>-lR</code>
Commands	<code>make</code>
Environment variables	<code>PATH</code>
File and pathnames	<code>/dev/null</code>
Function names	<code>exit()</code>
Keyboard chords	Ctrl-Alt-Delete
Keyboard input	<code>something you type</code>
Keyboard keys	Enter
Program output	<code>login:</code>
Programming constants	<code>NULL</code>

*continued...*

Reference	Example
Programming data types	<code>unsigned short</code>
Programming literals	<code>0xFF, "message string"</code>
Variable names	<code>stdin</code>
User-interface components	<b>Cancel</b>

We use an arrow (→) in directions for accessing menu items, like this:

You'll find the **Other...** menu item under **Perspective→Show View**.

We use notes, cautions, and warnings to highlight important messages:

Notes point out something important or useful.

**CAUTION:** Cautions tell you about commands or procedures that may have unwanted or undesirable side effects.

**WARNING:** Warnings tell you about commands or procedures that could be dangerous to your files, your hardware, or even yourself.

## Note to Windows users

In our documentation, we use a forward slash (/) as a delimiter in *all* pathnames, including those pointing to Windows files.

We also generally follow POSIX/UNIX filesystem conventions.

## Technical support options

To obtain technical support for any QNX product, visit the **Support + Services** area on our website ([www.qnx.com](http://www.qnx.com)). You'll find a wide range of support options, including community forums.

# *Chapter 1*

---

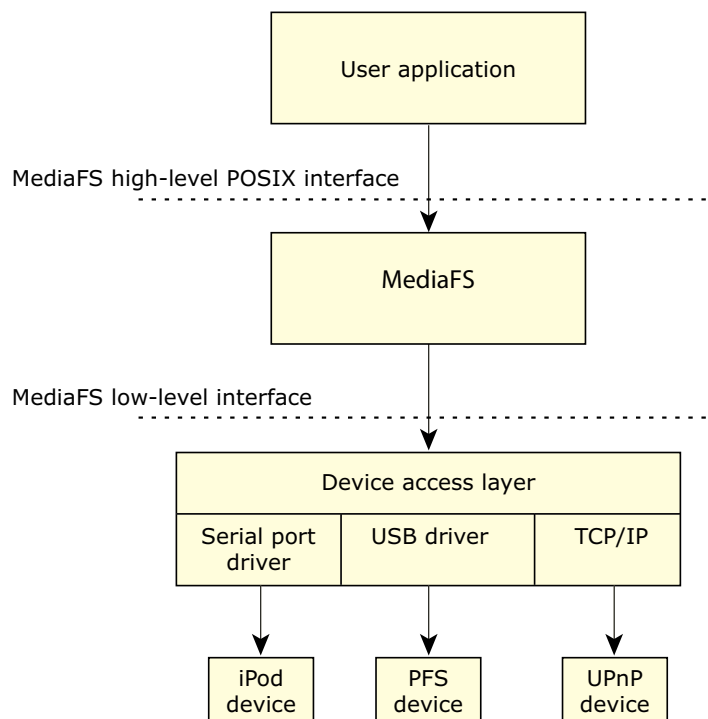

## **MediaFS Overview**

MediaFS presents a POSIX-compliant filesystem view of media devices. This filesystem view of media devices can be used by higher-level applications, such as the MME, to browse and control media devices. These higher-level applications can use the MediaFS standardized interface to query and control media playback on a wide range of media devices, including portable music devices such as iPods and PlaysForSure devices, and UPnP devices that attach to a network.

For more information about the MME, start with *Introduction to the MME*.

The following diagram shows the MediaFS module in relation to the user application and media devices.

#### *MediaFS in a multimedia implementation*

The MediaFS standardized interface allows higher-level multimedia applications, such as the MME, to use POSIX functions related to file and directory operations to access audio and video content along with associated metadata on media devices and mediastores.

To add a new device to a multimedia environment that uses MediaFS, all you need to do is:

- create a MediaFS implementation to represent the device according to the MediaFS requirements
- make adjustments to the client application (the MME or the HMI, or both) to ensure that they are aware of and able to handle new situations that might arise due to the presence of the new device

To create a MediaFS implementation you can use **io-fs**, a resource manger, or some other component as you require.

### *In this chapter...*

Filesystem location	7
The MediaFS filesystem structure	7
Required POSIX function support	8

This chapter describes:

- Filesystem location
- The MediaFS filesystem structure
- Required POSIX function support

## Filesystem location

When a MediaFS implementation learns of a new media device, it registers a path with the path space manager to the location of the MediaFS filesystem; this path is called the *mountpoint*. The MediaFS implementation then:

- creates the MediaFS standardized filesystem structure for the device
- creates a filesystem representing the device under `/fs`
- makes available the contents of the device as a filesystem with the root directory of the device mounted on `/fs/dev_id`, where *dev\_id* is a name that indicates the type of device with a numeric suffix representing the device's instance number

The first device discovered has an instance number of 0. For example, if a device is an iPod it is mounted as `/fs/ipod0`; while a PFS/MTP device is mounted as `/fs/pfs0`.

Multiple instances of a device are identified by their numeric suffixes. Thus, for example two iPods, one PFS device, and one UPnP device would be mounted as follows:

```
/fs/ipod0
/fs/ipod1
/fs/pfs0
/fs/upnp0
```

For more information about how to represent a media device to MediaFS, see the chapter MediaFS Entities.

For more information about resource managers, see the *Writing a Resource Manager* in the QNX Neutrino documentation set.

## The MediaFS filesystem structure

Located under the MediaFS mountpoint, the `.FS_info.` directory is the MediaFS standardized structure of files and directories that contain the control and state information of a media device. Every device instance has its own MediaFS filesystem structure.

The basic MediaFS filesystem structure is as follows:

```
Directories
Files
mountpoint
```

```

mountpoint/.FS_info.
mountpoint/.FS_info./info.xml
mountpoint/.FS_info./dev
mountpoint/.FS_info./current
mountpoint/.FS_info./control
mountpoint/.FS_info./playback

```

Media device controllers must populate the the device-specific files in the `.FS_info.` directory, according to the specifications presented in the chapter MediaFS Entities.

The figure below shows a MediaFS hierarchy with a Bluetooth device.

---

*The MediaFS module hierarchy with a Bluetooth device*

Files and directories outside the `.FS_info.` directory are device dependent and, therefore, do not have a standardized, defined structure in MediaFS. See “Directories and files outside the `.FS_info.` directory” in the chapter MediaFS Entities.

## Required POSIX function support

All files and folders in the MediaFS representation adhere to the POSIX standard, and the following POSIX functions must be supported on all directories and files in the MediaFS representation:

- `close()` — close a file
- `closedir()` — close a directory
- `devctl()` — control a device
- `dircntl()` — control an open directory
- `fstat()` — get file information, given a file description
- `open()` — open a file
- `opendir()` — open a directory
- `readdir()` — read a directory entry

- *stat()* — get information about a file or directory, given a path

Directories and files can be identified by using the standard POSIX *stat()* function, and the `S_ISDIR` and `S_ISREG` macros on the returned `stat` structure.

For speed optimizations, MediaFS should support the ability to retrieve extra *stat()* information as part of the *readdir()* operation, if the `D_FLAG_STAT` flag is set.

For more information about these functions and data structures, see the *QNX Neutrino Library Reference*.

### *In this chapter...*

The <code>.FS_info.</code> directory and its contents	13
Directories and files outside the <code>.FS_info.</code> directory	16
Playlist files and directories	18

This chapter describes:

- The `.FS_info.` directory and its contents
- Files outside the `.FS_info.` directory
- Playlist files and directories

## The `.FS_info.` directory and its contents

When a MediaFS implementation learns of a device, it creates a `.FS_info.` directory for the media device with device-specific playback and metadata interface items. The table below lists these items:

Item	Type	Required?	Description
<code>info.xml</code>	file	Yes	XML file with device-specific information.
<code>control</code>	file	Optional	File in which device-specific playback actions are issued to a media device.
<code>dev</code>	symbolic link	Optional	Symbolic link to device identified by the <code>&lt;uuid&gt;</code> element in the <code>info.xml</code> file.
<code>current</code>	symbolic link	Optional	Symbolic link pointing to the currently playing file in MediaFS.
<code>playback</code>	directory	Optional	Directory with symbolic links, listed in the same order as the media device will complete playback of the files.

See the sections below for complete descriptions of the `.FS_info.` items.

### The `info.xml` file

The `info.xml` device information file is an XML version 1.0 file that contains device-specific information. The MediaFS implementation creates this file when it creates the `.FS_info.` directory for a media device, placing it in the root directory for the device as `.FS_info./info.xml`. This file is static and persists for the lifetime of the MediaFS instance that created it.

To the client application, the `info.xml` file is a *read only* file. Client applications can *not* write to this file.

When it creates the `info.xml` file, MediaFS does *not* populate it with device information. To enable MediaFS to present to higher level software layers a standard interface to all media devices, device controllers must populate the `info.xml` file for each device with XML-formatted, device-specific information. This XML-formatted information can be used by higher-level software, such as the MME, and may also be useful for human viewing.

The table below lists the basic elements of an `info.xml` file:

XML Key	Required?	Description
<code>&lt;media&gt;</code>	Yes	Root XML key for the media
<code>&lt;media&gt;/&lt;device&gt;</code>	Yes	A name used to indicate to upper layer components the device below the MediaFS.
<code>&lt;media&gt;/&lt;serial&gt;</code>	Yes	Device serial number
<code>&lt;media&gt;/&lt;model&gt;/&lt;*&gt;</code>	Optional	Device model information
<code>&lt;media&gt;/&lt;protocol&gt;/&lt;*&gt;</code>	Optional	Device protocol information
<code>&lt;media&gt;/&lt;swversion&gt;</code>	Optional	Device software revision
<code>&lt;uuid&gt;</code>	Optional	A unique identifier for the media device; upper layer components, such as the MME, must be able to use this key to associate the media device with its settings and remember these settings. A <code>&lt;uuid&gt;</code> number must be static, and unique to a media device.

### Example `info.xml` file

The example below presents the minimum required content of a `info.xml` file:

```
<?xml version="1.0" standalone="yes"?>
<uuid>unique_media_identifier</uuid>
<media>
<device>devicename</device>
<serial>8N838BUH2C7</serial>
</media>
```

Mediastore changer devices, such as CD or DVD changers, require different elements in their `info.xml` file. For more information, see “The `info.xml` file for mediastore changers” in the chapter Working with Media Changers.

### The control file

The `control` file in the `.FS_info.` directory is the file where device-specific playback actions are issued to a media device. This MediaFS control file is a file interface that supports the following I/O capabilities:

- Accept playback and state information device control messages.
- Set a state via device control messages.
- Provide asynchronous change notifications via out-of-band messaging.
- Get events from the MediaFS event queue; see also the `DCMD_MEDIA_READ_EVENTS` device control message, and the chapter MediaFS Events.

The MediaFS control file provides state information and metadata for the current device. That is:

- state and metadata device control messages issued on the control file return information about the device at the time of the execution
- metadata obtained from the control file is the metadata for the currently active (playing) track

---

The **control** file is required for devices, such as iPods, that use serial (“two-wire”) connections. It is not required for devices, such as PFS devices and certain iPods, that use USB (“one-wire”) connections.

---

### Conditions for sending a notification

If the state or the metadata of the currently active device changes, the MediaFS control file should send a notification via an out-of-band message to all registered listeners, such as, for example, the MME.

The MediaFS control file sends a notification if *any* of the following conditions is met:

- Any data that will be returned in the **\_media\_playback\_status** structure has changed.
- An event has been added to the MediaFS event queue.
- The **current** file has been updated.
- The content of the **playback** directory has changed.
- The device playback speed or state has changed.

---

To receive asynchronous notifications, a client application must use the QNX *io\_notify()* function to register for these notifications.

---

### The *dev* symbolic link

The *dev* element in the **.FS\_info.** directory is a symbolic link to the media device identified by the **<uuid>** element. It should be an entry in the **/dev** directory and provide access directly to the media device.

---

Devices such as an HTTP client driver may not have a *dev* entry.

---

### The *current* symbolic link

The *current* symbolic link is optional. If it is present, this symbolic link is a relative path from the **.FS\_info.** directory which, when it is resolved, points to the currently active file. This active file is in the MediaFS file system.

If the `playback` directory is present, the symbolic link points to an entry in this directory. If no file on the media device is currently active, the *current* symbolic link is removed or deleted.

Metadata retrieval commands issued on the *current* symbolic link return the specified metadata for the currently playing file.

The MediaFS control file sends a notification to registered clients via an out-of-band message whenever the *current* symbolic link is updated.

---

A system must support the POSIX `readlink()` function in order to resolve the *current* symbolic link.

---

## The `playback` directory

The `playback` directory is optional. If it is present, this directory contains symbolic links to files that the media device will play. When it writes these symbolic links to the `playback` directory, the device controller should organize them in the same order as the media device will play the files referenced by the links.

Whenever possible, symbolic links in the `playback` directory should point to the files that they represent in the main media filesystem. However, for some operational modes on some devices, the device may not be able to guarantee the accuracy of these pointers. Client applications should, therefore, treat the links as hints and not as guarantees of a file's location in the main media filesystem.

### Metadata retrieval

Client applications can use metadata retrieval messages to execute metadata extraction calls against the files listed in the `playback` directory. If the links point into the MediaFS hierarchy, the results of a call to one of these symbolic links is the same as the result of a call to retrieve metadata directly from a file in MediaFS.

For more information about metadata retrieval messages, see the chapter Metadata Messages.

### Changes to the `playback` directory

When the content of the `playback` directory changes (because, for example, the client has selected a play operation against a new set of media files), the control file sends a notification of the change to all applications registered for out-of-band messages on the `control` file.

## Directories and files outside the `.FS_info.` directory

The behavior of MediaFS entities located outside the `.FS_info.` directory structure varies according to the capabilities and behaviors of each underlying media device. However, MediaFS maintains some behaviors throughout for these directories and files, as described in this section.

## Directory behavior

MediaFS directories outside the `.FS_info.` directory represent the data hierarchy of the target device. For example, directories on an Apple iPod could be represented using the following structure:

```
/ipod0
/ipod0/.FS_info.
/ipod0/Music
/ipod0/Music/Artists
/ipod0/Music/Songs
...
```

## Directory characteristics

To be usable by MediaFS, a directory outside the `.FS_info.` directory structure must have the following characteristics:

- The directory must be of the type `S_ISDIR`.
- The directory must support the `DCMD_FSYS_DIR_NFILES` command message, to indicate the number of files present in the directory.
- All directory attributes (name, size, etc.) must adhere to the QNX filesystem specifications and POSIX specifications.

Additionally, directories outside the `.FS_info.` directory structure may need to accept the `DCMD_MEDIA_PLAY` command, if the associated media device supports playback of all items in a directory; that is, if the device supports using a directory as a playlist.

## File behavior

MediaFS files outside the `.FS_info.` directory represent files or tracks that can be used with the media device.

The POSIX filesystem representation for these files is free-form, with the following restrictions:

- Files must be of the type `S_ISREG`.
- Files should use a file extension to aid in file type detection.
- All file attributes (name, size, etc.) must adhere to QNX filesystem specifications and POSIX specifications.

## Supported device control messages

MediaFS files outside the `.FS_info.` directory structure must support state change and metadata query device control messages.

Messages issued directly to a file outside this directory structure must apply to the specified file. For example, the device control message `DCMD_MEDIA_SONG` issued

directly to a file outside the `.FS_info.` directory structure returns the song title for that file, *not* the song title of the currently playing file.

If a device control message cannot be completed due to media device limitations, the call that issues the control message returns an ENOTSUP error.

For a complete list of device control messages used with MediaFS and descriptions of these messages, see the chapters Playback Messages and Metadata Messages.

## Playlist files and directories

A playlist can be either of:

- a standardized playlist file, such as an M3U or PLS file, stored in the MediaFS hierarchy; entries in these playlist files must be filesystem paths pointing to entries in MediaFS
- a MediaFS playlist, which is a collection of files inside a directory

---

Playlist support is subject to upper layer component (MME) support.

---

### MediaFS playlists

Note the following about MediaFS playlists:

- A MediaFS playlist directory can be present only *outside* of the `.FS_info.` directory.
- For a directory to be identified as a MediaFS playlist, the directory must have the *others* execute bit cleared in the `st_mode` member of its `stat` structure.

### Identifying a MediaFS playlist

The code snippet below shows how to determine if a directory is a MediaFS playlist:

```
stat(path, &statbuf);
if ((S_ISDIR ! S_IXOTH) & statbuf.st_mode)==S_ISDIR) {
    //This is a MediaFS playlist
}
```

For more information about the `stat` structure, see `stat()`, `stat64()` in the the *QNX Neutrino Library Reference*.

***In this chapter...***

Representing media changers and mediastores	21
Informing MediaFS of state changes	23

Media changer devices — essentially CD and DVD changers — differ from other media devices because they contain and change *removable mediastores*.

A removable mediastore is a physical storage medium, such as a CD or DVD, with one or more media files that can be synchronized and played. Media changer devices can load and unload these mediastores as required, changing their states from “unavailable” to “available” to “active”.

This chapter describes how these devices and their mediastores can be represented to MediaFS, and how state changes on these devices should be communicated to MediaFS:

- Representing media changers and mediastores
- Informing MediaFS of state changes

## Representing media changers and mediastores

MediaFS uses extensions to offer a common representation of devices with multiple mediastores — devices such as CD and DVD changers. It represents a media changer device as a single *changer* container. This changer container includes multiple *slot* items. Each slot represents one mediastore (such as a CD or a DVD), and is described by a separate MediaFS instance.

For example, the following illustration represents the hierarchy of one media changer device with three slots, each slot described by a MediaFS instance:

---

*MediaFS changer device and mediastore hierarchy representation*

### MediaFS instances for slots

A slot represents a single mediastore. Each slot has a MediaFS instance, which adheres to the MediaFS specifications for media device representation. That is, each slot has a MediaFS instance with its own **info.xml** file, **control** file, optional **playback** directory, *dev* symbolic link, and optional *current* symbolic link.

#### The **info.xml** file for mediastore changers

MediaFS **info.xml** files for changer devices and slots differ from **info.xml** files for other media devices in order to accurately represent the devices as containers for the mediastores, and the mediastores as dependent on a device. That is, the **info.xml** files for changer devices and slots must indicate that the changer device can hold one, many or no mediastores, and that these mediastores can only be accessed inside a changer.

The table below lists the elements required in an `info.xml` file use to describe media changer devices and slots:

XML Key	Required?	Description
<code>&lt;media&gt;</code>	Yes	Root XML key for the media
<code>&lt;media&gt;/&lt;driver&gt;</code>	Yes	Description of the device as a MediaFS changer device
<code>&lt;media&gt;/&lt;name&gt;</code>	Yes	Name of the mediastore
<code>&lt;media&gt;/&lt;serial&gt;</code>	Yes	Device serial number
<code>&lt;media&gt;/&lt;slot&gt;</code>	Yes	Slot number for the mediastore
<code>&lt;media&gt;/&lt;type&gt;</code>	Yes	Description of the mediastore type

### Required XML keys

The keys listed below are required in the `info.xml` file for a media changer device slot:

#### `<media>/<driver>`

A user-defined name for the device; for slots this value *must* be set to `mediafs-changer`.

#### `<media>/<name>`

The mediastore name that can be passed to the upper software layers (such as the MME and an HMI) for display to the user. In most cases this name is the volume name of the mediastore.

#### `<media>/<serial>`

A unique identifier for the mediastore represented by the slot. It must be set to a value , such as the freeDB hash, that uniquely identifies the mediastore.

#### `<media>/<slot>`

The slot position of the mediastore in the changer device. The value of this key must be the same as the offset returned by a call to the device with the `DCMD_CAM_MECHANISM_STATUS` control message. This offset (and therefore the value of the `<slot>` key) is a single-digit string representing the slot with the mediastore.

#### `<media>/<type>`

A predefined text value identifying the kind of mediastore present in the media changer device slot. Permitted values are:

- FS — basic filesystem
- AUDIOCD — CDDA disc
- DVDVIDEO — DVD-video disc

- DVDAUDIO — DVD-audio disc
- VCD — Video CD disc
- UNKNOWN — unknown mediastore type

#### Example `info.xml` file

The example below shows an `info.xml` file for a MediaFS slot representing a mediastore changer device:

```
<?xml version="1.0" standalone="yes"?>
<info>
  <media>
    <device>mediafs-changer</device>
    <slot>1</slot>
    <serial>280a1752</serial>
    <name>MIXED</name>
    <type>FS</type>
  </media>
  <device>
    <driver>mediafs-changer</driver>
    <category>media</category>
  </device>
</info>
```

For more information about the `info.xml` file, see “The `info.xml` file” in the chapter MediaFS Entities.

## Informing MediaFS of state changes

MediaFS expects a slot to have one of the following states:

- unavailable — the slot is not represented in MediaFS
- available — the slot is represented in MediaFS, inside the changer container
- active — the slot is available *and* a mediastore that can be synchronized and played is physically present

For example, if a CD changer has six possible mediastore locations, it can be represented by a changer with any one of slots 0 to 5. If a mediastore is loaded into slot 0, MediaFS represents it as shown in the figure below:

```
/fs/changer
└─ slot 0
```

---

*MediaFS changer representation of a mediastore in slot 0*

If the mediastore is ejected from the changer, MediaFS removes its slot representation:

```
/fs/changer
```

---

*MediaFS changer representation of device with no available mediastores*

For files on a mediastore to be synchronized or played, the slot representing the mediastore in MediaFS must be marked *active* as well as available. That is, the device controller must use the slot's `control` file to inform MediaFS not only that the slot is present, but that a readable disc is physically loaded in the changer and is ready to be read. Thus, only one changer slot can be active at any one time.

## Changer states

To get the current changer state from MediaFs, the client application or the device controller must issue the `DCMD_CAM_CDROM_MECHANISM_STATUS` device control message to each changer slot's `control` file, as appropriate.

`DCMD_CAM_CDROM_MECHANISM_STATUS` is a standard control defined in the `sys/cdrom.h` header file. The example below shows one way to implement the `DCMD_CAM_CDROM_MECHANISM_STATUS` device control command:

```
#define CDROM_MSH_CHANGER_SET_CURRENT_SLOT( cdrom_status, slot )\
    cdrom_status.mech_state      &= ~0x07          ; \
    cdrom_status.changer_state_slot &= ~0x1F        ; \
    cdrom_status.mech_state      |= (slot >> 5)     ; \
    cdrom_status.changer_state_slot |= (slot & 0x1F) ;

struct _cdrom_mechanism_status  cdrom_status ;
struct _cdrom_exchange         cdrom_exchange ;

switch(changer.status)
{
case STATUS_EMPTY:
    cdrom_status.hdr.mech_state = CDROM_MSH_MECHANISM_IDLE ;
    break;
case STATUS_RETRACT:
case STATUS_LOAD:
    cdrom_status.hdr.changer_state_slot = CDROM_MSH_CHANGER_LOADING ;
    break;
case STATUS_UNLOAD:
    cdrom_status.hdr.changer_state_slot = CDROM_MSH_CHANGER_UNLOADING ;
    break;
default:
    cdrom_status.hdr.changer_state_slot = CDROM_MSH_CHANGER_READY ;
    break;
}

cdrom_status.hdr.num_slots_avail = changer.num_slots ;
cdrom_status.hdr.slot_table_len  = changer.num_slots ;

for( index=0; index < changer.num_slots; index++ ) {
    if(changer.slotInfo[index].status == DISCIN) {
```

```
        cdrom_status.str[index].flags |= CDROM_STR_DISC_PRESENT;
    }
}

CDROM_MSH_CHANGER_SET_CURRENT_SLOT( cdrom_status.hdr,
                                     changer.active_slot);
```

***In this chapter...***

Requested playback control sequences	29
Managing autonomous playback state changes	33

Playback on media devices may be initiated or changed by:

- a user; that is, a high-level application, such as the MME
- a media device, such as an iPod

This chapter presents the control message sequences and the settings that a device controller may need to support to monitor and manage media playback through *devctl()* calls to MediaFS entities. It contains the following sections:

- Requested playback control sequences
- Managing autonomous playback state changes

For a list of MediaFS control messages, see the chapters Playback Messages and Metadata Messages.

## Requested playback control sequences

A media device controller using MediaFS should support client applications issuing commands to MediaFS entities to start playback of:

- a media file (track), at the start of the track or at an offset, if the media device supports playback from an offset
- a directory
- a media device, if the media device supports this action

This section presents the control message sequences and settings required to effect a playback state change through a *devctl()* call to a MediaFS entity. It contains:

- Start playback — file or directory
- Start playback — media device
- Fast forward and reverse
- Pause and resume playback

### Start playback — file or directory

To start playback for a specific file or directory, the client application should issue, as required, either the `DCMD_MEDIA_PLAY` or the `DCMD_MEDIA_PLAY_AT` device control message to the MediaFS file or directory to play.

If the file or directory is valid for the media device, the device controller must perform the following operations, in sequence:

- 1 Receive the device control message, and validate playback.
- 2 Start playback of the requested track on the media device.
- 3 Update the following `_media_playback` structure members:

- *count* — set to the number of tracks that will be played
  - *index* — set to the index of the requested track
  - *state* — set to `PLAYBACK_STATE_PLAY`
  - *flags* — if the media device supports this feature, set to `PLAYBACK_FLAG_SPEED_EXACT` *only*; if the device does not support this feature, set to 0 (zero)
  - *metaseq* — set to 0 (zero)
  - *length* — set to the length of the track, or to 0 (zero) if the track length is not available
  - *elapsed* — set to 0 (zero) if the `DCMD_MEDIA_PLAY` message was issued, or to the track start offset, in seconds, if the `DCMD_MEDIA_PLAY_AT` message was issued and is supported
  - *speed* — if the the *flags* member is set to `PLAYBACK_FLAG_SPEED_EXACT`, set to 1 (one) *only*; no other value is permitted
- 4 Update the MediaFS *current* symbolic link (if it is present) to point to the requested media file.
  - 5 Send an out-of-band notification on the `control` file.
  - 6 If all operations are successful, reply to the device control message with EOK.

## Start playback — media device

Some media devices support playback of the entire device, starting with the first track in the device, a random track, or at the point where playback was previously stopped. To start or resume playback of a device, a client application should issue the `DCMD_MEDIA_PLAY` device control message to the MediaFS `control` file.

If this action is valid for the current media device, the device controller must perform the following operations, in sequence:

- 1 Receive the device control message, and validate playback.
- 2 Start playback of the media device.
- 3 Update the following `_media_playback` structure members:
  - *count* — set to either 1 (one) if only one track will be played, or to the number of tracks that will be played
  - *index* — set to the currently playing track if the device provides this information immediately, or to 0 (zero) if the information is not provided at this time
  - *state* — set to `PLAYBACK_STATE_PLAY`
  - *flags* — if the media device supports this feature, set to `PLAYBACK_FLAG_SPEED_EXACT` *only*; no other value is permitted

- *metaseq* — set to 0 (zero)
  - *length* — set to the length of the track, or 0 (zero) if the length is unavailable
  - *elapsed* — set to 0 (zero)
  - *speed* — set to 1 (one), *only* if the `PLAYBACK_FLAG_SPEED_EXACT` flag is set; no other value is permitted
- 4 Update the *current* symbolic link to point to the requested media file. If the currently playing file is not known at this time, clear the symbolic link.
  - 5 Send an out-of-band notification on the `control` file.
  - 6 If all operations are successful, reply to the device control message with EOK.

### Track information updates

If a device autonomously indicates the playing track *after* MediaFS has replied to the `DCMD_MEDIA_PLAY` device control message that started playback, the device controller must perform the following operations, in sequence:

- 1 Update the following `_media_playback` structure members:
  - *count* — set to either 1 (one) if only one track will be played, or to the number of tracks that will be played
  - *index* — set to the currently playing track
  - *metaseq* — increment by 1 (one), if metadata is now available
  - *length* — set to the length of the track, or 0 (zero) if the length is unavailable
  - *elapsed* — set to the current track time received from the media device
- 2 Send an out-of-band notification on the `control` file.

### Fast forward and reverse

The playback speed or direction of a media device represented through MediaFS can be changed only while the device is in the playing state. To change the playback speed or direction, or both, the client application should issue the appropriate messages to the the MediaFS `control` file.

If the action is valid for the current media device, the device controller must perform the following operations, in sequence:

- 1 Receive the device control message, and validate playback.
- 2 Change the playback speed on the media device, as requested.
- 3 Update the following `_media_playback` structure members:
  - *state* — set to `PLAYBACK_STATE_PLAY` (1)
  - *flags* — set to `PLAYBACK_FLAG_FASTFWD` or `PLAYBACK_FLAG_Fastrwd`, and set to `PLAYBACK_FLAG_SPEED_EXACT` if the device supports this feature

- *speed* — set to the playback speed, *only* if the `PLAYBACK_FLAG_SPEED_EXACT` flag is set
- 4 Send an out-of-band notification on the `control` file.
  - 5 If all operations are successful, reply to the device control message with EOK.

For more information about fast forward and reverse control messages, see the chapter Playback and Status Messages.

## Pause and resume playback

The client application should pause and resume playback on MediaFS devices by issuing messages to the MediaFS `control` file. If these actions are valid for the current media device, the device control should apply them to the device.

### Pause playback

Playback can only be paused while a device is in the playing state. To pause playback, a client application should issue the `DCMD_MEDIA_PAUSE` message to the MediaFS `control` file. If this action is valid for the current media device, the device controller must perform the following operations, in sequence:

- 1 Receive the device control message, and validate playback.
- 2 Pause playback on the media device.
- 3 Update the following `_media_playback` structure members:
  - *state* — set to `PLAYBACK_STATE_PAUSE`
  - *speed* — set to 0 (zero), *only* if the `PLAYBACK_FLAG_SPEED_EXACT` flag is set
- 4 Send an out-of-band notification on the `control` file.
- 5 If all operations are successful, reply to the device control message with EOK.

### Resume playback

Playback can only be resumed while the device is in the paused state. To resume playback, the client application should issue the `DCMD_MEDIA_RESUME` message to the MediaFS `control` file. If this action is valid for the current media device, the device controller must perform the following operations, in sequence:

- 1 Receive the device control message, and validate playback.
- 2 Resume playback paused on the media device.
- 3 Update the following `_media_playback` structure members:
  - *state* — set to `PLAYBACK_STATE_PLAY`
  - *speed* — set to the device speed, *only* if the `PLAYBACK_FLAG_SPEED_EXACT` flag is set

- 4 Send an out-of-band notification on the `control` file.
- 5 If all operations are successful, reply to the device control message with EOK.

## Managing autonomous playback state changes

During playback, a media device may change playback or metadata states autonomously, independently of any user request. This section describes the actions that a device controller must perform when it encounters a device-initiated state change:

- Track change
- Playback state change
- Metadata update

### Track change

If a media device autonomously changes tracks, the device controller must perform the following operations, in sequence:

- 1 Update the following `_media_playback` structure members:
  - *count* — set to the number of tracks that will be played
  - *index* — set to the new currently playing track
  - *metaseq* — set to 0
  - *length* — set to the length of the track, or 0 (zero) if the length is unavailable
  - *elapsed* — set to 0 (zero)
- 2 Update the *current* symbolic link to point to the new currently playing MediaFS file.
- 3 Send an out-of-band notification on the `control` file.

### Playback state change

Some media devices may autonomously pause, stop, or resume playback. If these state changes occur on a media device, the device controller must perform the following operations, in sequence:

- 1 Update the following `_media_playback` structure members:
  - *state* — set to the new playback state
  - *speed* — set to the device speed, *only* if the `PLAYBACK_FLAG_SPEED_EXACT` flag is set
- 2 Send an out-of-band notification on the `control` file.

## Metadata update

If a media device supports asynchronous metadata updates, it may update the metadata for the current playing track. If an update of this type occurs, the device controller must perform the following operations, in sequence:

- 1 Update the following `_media_playback` structure member:
  - *metaseq* — increment by 1 (one)
- 2 Send an out-of-band notification on the `control` file.

Subsequent client application requests for metadata (made through a device control message to a MediaFS entity) will retrieve the new metadata that was received from the media device.

### *In this chapter...*

Using device control messages	37
Device configuration messages	38
iPod, UPnP device and streaming messages	39

This chapter describes the MediaFS device control messages and how to use them. It contains the following sections:

- Using device control messages
- Device configuration messages
- iPod, UPnP device, and streaming messages

- 
- The MediaFS device control messages, constants and data structures are defined in the header file `io-fs/lib/public/sys/dcmd_media.h`.
  - If a buffer is required for a command message, this documentation includes a buffer description with the message description; the buffer description follows the template: “Buffer: *description*”. If the control message does not require a buffer, then no buffer description is presented with the message description.
  - For information about how to use MediaFS device control messages, see “Using device control messages” below.
  - For information about the messages used to retrieve album art, see “Album art retrieval messages” in the chapter Getting Album Art.
- 

## Using device control messages

MediaFS device control messages can be applied to open files and directories in the MediaFS filesystem to:

- query media devices for their states and playback information
- initiate actions against media files, such as start, pause and stop playback, skip to the next or previous file, or change random and repeat mode settings
- retrieve file metadata
- extract album art and other images

Control messages are applied by calls to the `devctl()` function. When a control message is applied to a MediaFS entity, the filesystem routes the message to the appropriate device driver. The device driver must:

- apply the requested action to the underlying media device
- return to the calling application the the result of the action

All state modification control messages must be synchronous. A requested action must either complete or fail before returning. For example, if the state modifier `DCMD_MEDIA_PLAY` message is issued, upon return of the `devctl()` call, the underlying device must be in a playing state, or have returned a POSIX error indicating why the command failed.

As with other directories and files, an application must open a MediaFS directory or file with, respectively, the *opendir()* and the *open()* functions before it can use the *devctl()* function to issue control messages to them.

To pass data to and receive data from media devices, a client application should use the *devctl()* function's *dev\_data\_ptr* and *dev\_info\_ptr* arguments to point to the appropriate *\_media\_\** data structures. These *\_media\_\** structures are described in the chapter Playback Structures and Constants.

For a list of POSIX functions that MediaFS supports, see “Required POSIX function support” in the chapter MediaFS Structure. For more information about the functions, such as *open()* and *devctl()*, used to control devices, see the *QNX Neutrino Library Reference*.

## Device configuration messages

This section describes the device messages defined to get and set device configurations. These message are:

- DCMD\_MEDIA\_GET\_XML
- DCMD\_MEDIA\_SET\_XML

### DCMD\_MEDIA\_GET\_XML

DCMD\_MEDIA\_GET\_XML returns an XML configuration string (UTF-8) with the device configuration information. See also the chapter MediaFS Entities.

Buffer: **char[1]**

### DCMD\_MEDIA\_SET\_XML

DCMD\_MEDIA\_SET\_XML expects a buffer containing a terminated xpath string followed by a terminated value string; that is, the element or attribute to modify, and its new value.

Buffer: **char[1]**

---

DCMD\_MEDIA\_GET\_XML and DCMD\_MEDIA\_SET\_XML use a common configuration layout that becomes specific for each device. For example:

```
<device api_version="1">
  <media>
    <interface type="usb" ... />
    <DeviceSpecificString>
      .... Device specific settings
    </DeviceSpecificString>
  </media>
</device>
```

See also the chapter MediaFS Entities.

---

## iPod, UPnP device and streaming messages

This section describes the device control messages defined to obtain information from and manage iPod and UPnP devices, and media streams. These message are:

- Common messages
- iPod device messages
- UPnP device messages
- Media stream messages

---

Most devices do not support the full set of control messages. If a device does not support a requested action, the device controller must return the error code ENOTSUP (command invalid for this device).

---

### Common messages

This section describes the device control messages that can be used to obtain information from and manage iPod devices, UPnP devices, DRM, and media streams. These messages are:

- DCMD\_MEDIA\_CONFIG
- DCMD\_MEDIA\_GET\_DEVINFO

#### DCMD\_MEDIA\_CONFIG

DCMD\_MEDIA\_CONFIG issues a configuration setting to a media device.

Buffer: `char[1]`

## DCMD\_MEDIA\_GET\_DEVINFO

DCMD\_MEDIA\_GET\_DEVINFO requests information about a media device.

Buffer: `char[8*1024]`

## iPod device messages

This section describes the device control messages defined to obtain information from and manage iPod devices. These message are:

- DCMD\_MEDIA\_IPOD\_DAUDIO
- DCMD\_MEDIA\_IPOD\_CAP
- DCMD\_MEDIA\_IPOD\_TAG

### DCMD\_MEDIA\_IPOD\_DAUDIO

DCMD\_MEDIA\_IPOD\_DAUDIO is used to retrieve iPod audio settings from an iPod device. This information is carried in the `_media_ipod_daudio` data structure

Buffer: `struct _media_ipod_daudio`

### DCMD\_MEDIA\_IPOD\_CAP

DCMD\_MEDIA\_IPOD\_CAP retrieves capabilities information from an iPod device.

Buffer: `char[1]`

### DCMD\_MEDIA\_IPOD\_TAG

DCMD\_MEDIA\_IPOD\_TAG is used to add an iTunes tag to a file on an iPod device.

Buffer: `uint8_t[1]`

## UPnP device messages

This section describes the device control messages defined to obtain information from and manage UPnP devices. These message are:

- DCMD\_MEDIA\_UPNP\_CDS\_BROWSE

### DCMD\_MEDIA\_UPNP\_CDS\_BROWSE

DCMD\_MEDIA\_UPNP\_CDS\_BROWSE browses a mediastore on a device that uses the UPnP protocol.

Buffer: `char[8]`

## Media stream messages

This section describes the device control messages defined to obtain information from and manage media streams. These message are:

- DCMD\_MEDIA\_CLOSE\_STREAM

- DCMD\_MEDIA\_INFO\_STREAM
- DCMD\_MEDIA\_OPEN\_STREAM
- DCMD\_MEDIA\_READ\_STREAM
- DCMD\_MEDIA\_SET\_STREAM

#### DCMD\_MEDIA\_CLOSE\_STREAM

DCMD\_MEDIA\_CLOSE\_STREAM closes a media stream.

#### DCMD\_MEDIA\_INFO\_STREAM

DCMD\_MEDIA\_INFO\_STREAM retrieves information about a media stream. This information must be placed in a `_media_stream_info` structure.

Buffer: `struct _media_stream`

#### DCMD\_MEDIA\_OPEN\_STREAM

DCMD\_MEDIA\_OPEN\_STREAM opens a media stream.

#### DCMD\_MEDIA\_READ\_STREAM

DCMD\_MEDIA\_READ\_STREAM reads a media stream into a buffer. Before a stream can be read, it must be opened with a DCMD\_MEDIA\_OPEN\_STREAM message and set with a DCMD\_MEDIA\_SET\_STREAM message.

Buffer: `char[16*1024-1]`

#### DCMD\_MEDIA\_SET\_STREAM

DCMD\_MEDIA\_SET\_STREAM sets the media stream that will be read by calls to `devctl()` with the DCMD\_MEDIA\_READ\_STREAM message.

Buffer: `unsigned int`

## *Chapter 7*

---

# **Playback Messages**

This chapter describes the MediaFS device control messages defined to retrieve state information from and control playback on a media device accessed and managed through MediaFS, or that are outside MediaFS. These message are:

- DCMD\_MEDIA\_ACCESS\_TYPE
- DCMD\_MEDIA\_FASTFWD
- DCMD\_MEDIA\_Fastrwd
- DCMD\_MEDIA\_GET\_REPEAT
- DCMD\_MEDIA\_GET\_SHUFFLE
- DCMD\_MEDIA\_GET\_STATE
- DCMD\_MEDIA\_NEXT\_CHAP
- DCMD\_MEDIA\_NEXT\_TRACK
- DCMD\_MEDIA\_PAUSE
- DCMD\_MEDIA\_PLAY
- DCMD\_MEDIA\_PLAY\_AT
- DCMD\_MEDIA\_PLAYBACK\_INFO
- DCMD\_MEDIA\_PLAYBACK\_STATUS
- DCMD\_MEDIA\_PREV\_CHAP
- DCMD\_MEDIA\_PREV\_TRACK
- DCMD\_MEDIA\_RESUME
- DCMD\_MEDIA\_SEEK\_CHAP
- DCMD\_MEDIA\_SET\_REPEAT
- DCMD\_MEDIA\_SET\_SHUFFLE
- DCMD\_MEDIA\_SET\_STATE

Playback control and device status messages can be issued to the MediaFS **control** file *only*.

The exceptions to this rule are:

- the DCMD\_MEDIA\_PLAY message, which can be issued to:
  - the MediaFS **control** file
  - a MediaFS file or directory
  - any other file

- a directory, if the device supports directory playback
- the DCMD\_MEDIA\_PLAY\_AT message, which can be issued to:
  - a MediaFS file

- Most devices do not support the full set of control messages. If a message is not supported by the media device the requested action, the device controller must return the error code ENOTSUP (command invalid for this device).
- All state modification control messages must be synchronous; the requested action must either complete or fail before returning.  
For example, if the state modifier DCMD\_MEDIA\_PLAY is issued, upon return of the *devctl()* call, the underlying device must be in a playing state, or have returned a POSIX error indicating why the command failed.

## DCMD\_MEDIA\_ACCESS\_TYPE

DCMD\_MEDIA\_ACCESS\_TYPE retrieves information about how a file is to be accessed. The status values may indicate that the file is known to be either DRM protected or *not* DRM protected, as well as whether a POSIX *read()* function can be used to access the file's media content.

This command does not use a data transfer buffer. If the *devctl()* status is EOK, the integer return value (obtained using the last parameter of the *devctl()* function) may contain a combination of the following values:

Type	Value	Description
ACCESS_TYPE_DRM_PROTECTED	1	The file is known to be DRM protected. May <i>not</i> be combined with ACCESS_TYPE_DRM_UNPROTECTED.
ACCESS_TYPE_DRM_UNPROTECTED	2	The file is known to not be DRM protected. May <i>not</i> be combined with ACCESS_TYPE_DRM_PROTECTED.
ACCESS_TYPE_READ_SUPPORTED	4	The file can be read using POSIX read functions (the file is not Zune). May be combined with ACCESS_TYPE_DRM_UNPROTECTED <i>or</i> with ACCESS_TYPE_DRM_PROTECTED.

## DCMD\_MEDIA\_FASTFWD

DCMD\_MEDIA\_FASTFWD instructs the media device to go to the fast forward speed specified by the *rate* member of the `_media_speed` structure. Behavior when this message is issued to a media device that is not in a playing state is device dependent: the request may succeed or fail, depending on the media device's capabilities and characteristics.

Buffer: `struct _media_speed`

## DCMD\_MEDIA\_Fastrwd

DCMD\_MEDIA\_Fastrwd instructs the media device to go to the fast reverse speed specified by the `_media_speed` data structure's *rate* member. Behavior when this message is issued to a media device that is not in a playing state is device dependent: the request may succeed or fail, depending on the media device's capabilities and characteristics.

Buffer: `struct _media_speed`

## DCMD\_MEDIA\_GET\_REPEAT

DCMD\_MEDIA\_GET\_REPEAT queries the media device for its current repeat playback mode. Defined repeat modes are:

- REPEAT\_OFF
- REPEAT\_ONE\_TRACK
- REPEAT\_ALL\_TRACKS
- REPEAT\_FOLDER
- REPEAT\_SUBFOLDER

On success, the call must return the current device repeat mode, in the `_media_settings` data structure's *value* member.

Buffer: `struct _media_settings`

## DCMD\_MEDIA\_GET\_SHUFFLE

DCMD\_MEDIA\_GET\_SHUFFLE queries the media device for its current random playback mode. Defined random modes are:

- SHUFFLE\_OFF
- SHUFFLE\_TRACKS
- SHUFFLE\_ALBUMS
- SHUFFLE\_FOLDER
- SHUFFLE\_SUBFOLDER

On success, the call must return the current device random mode, in the `_media_settings` data structure's *value* member.

Buffer: `struct _media_settings`

### DCMD\_MEDIA\_GET\_STATE

DCMD\_MEDIA\_GET\_STATE queries the media device for its current settings and returns the data in the `_media_settings` data structure. This data can be used at a later time to restore playback to the state at the time of the query.

Buffer: `uint8_t[1]`

### DCMD\_MEDIA\_NEXT\_CHAP

DCMD\_MEDIA\_NEXT\_CHAP instructs the media device to skip forward to the next chapter in a video. Behavior when this message is issued to a media device that is not in a playing state is device dependent: the request may succeed or fail, depending on the media device's capabilities and characteristics.

### DCMD\_MEDIA\_NEXT\_TRACK

DCMD\_MEDIA\_NEXT\_TRACK instructs the media device to skip forward to the next file in its playlist. Behavior when this message is issued to a media device that is not in a playing state is device dependent: the request may succeed or fail, depending on the media device's capabilities and characteristics.

### DCMD\_MEDIA\_PAUSE

DCMD\_MEDIA\_PAUSE instructs the media device to pause playback of the current file. Issuing this message always causes a "pause" instruction to be sent to the media device, *even when playback is already in a paused state*.

### DCMD\_MEDIA\_PLAY

DCMD\_MEDIA\_PLAY directs a media device to start playback. Behavior depends on the entity to which this message is issued, as follows:

- file — start or resume playback of the current file
- directory — start or resume playback of the file in the directory, as specified by the media device
- control file — start or resume playback of a track determined by the media device

### DCMD\_MEDIA\_PLAY\_AT

DCMD\_MEDIA\_PLAY\_AT instructs the media device to start playback at a specified time offset in a file. This play time offset is set in the `_media_play` data structure.

Buffer: `struct _media_play`

## DCMD\_MEDIA\_PLAYBACK\_INFO

DCMD\_MEDIA\_PLAYBACK\_INFO queries the media device for its current playback information and returns the data in the `_media_playback` data structure.

All media devices must support this capability, as it is fundamental to executing playback.

Buffer: `struct _media_playback`

## DCMD\_MEDIA\_PLAYBACK\_STATUS

DCMD\_MEDIA\_PLAYBACK\_STATUS queries the media device for its current playback status and returns the data in the `_media_playback_status` data structure.

All media devices must support this capability, as it is fundamental to executing playback.

Buffer: `struct _media_playback_status`

## DCMD\_MEDIA\_PREV\_CHAP

DCMD\_MEDIA\_PREV\_CHAP instructs the media device to skip back to the previous chapter in a video. Behavior when this message is issued to a media device that is not in a playing state is device dependent: the request may succeed or fail, depending on the media device's capabilities and characteristics.

## DCMD\_MEDIA\_PREV\_TRACK

DCMD\_MEDIA\_PREV\_TRACK instructs the media device to skip backward to the previous file in its playlist. Behavior when this message is issued to a media device that is not in a playing state is device dependent: the request may succeed or fail, depending on the media device's capabilities and characteristics.

## DCMD\_MEDIA\_RESUME

DCMD\_MEDIA\_RESUME instructs the media device to resume the playback of the current file. Issuing this message always causes a "resume" instruction to be sent to the media device, *even when playback has already resumed*.

## DCMD\_MEDIA\_SEEK\_CHAP

DCMD\_MEDIA\_SEEK\_CHAP instructs the media device to seek to the specified chapter in a video. Behavior when this message is issued to a media device that is not in a playing state is device dependent: the request may succeed or fail, depending on the media device's capabilities and characteristics.

Buffer: `uint32_t`

### DCMD\_MEDIA\_SET\_REPEAT

DCMD\_MEDIA\_SET\_REPEAT sets the repeat mode on the media device. For a list of defined repeat modes, see DCMD\_MEDIA\_GET\_REPEAT above.

Buffer: **struct \_media\_settings**

### DCMD\_MEDIA\_SET\_SHUFFLE

DCMD\_MEDIA\_SET\_SHUFFLE sets the random (shuffle) mode on the media device, changing the playback order. For a list of defined random modes, see DCMD\_MEDIA\_GET\_SHUFFLE above.

Buffer: **struct \_media\_settings**

### DCMD\_MEDIA\_SET\_STATE

DCMD\_MEDIA\_SET\_STATE restores the playback settings on the media device to the values stored in the **\_media\_settings** data structure by a *devctl()* call with the DCMD\_MEDIA\_GET\_STATE message.

Buffer: **uint8\_t[1]**

## ***Chapter 8***

---

# **Metadata Messages**

This chapter describes the MediaFS device control messages defined to obtain media file metadata from a media device accessed and managed through MediaFS, or that are outside MediaFS. These message are:

- DCMD\_MEDIA\_ALBUM
- DCMD\_MEDIA\_ARTIST
- DCMD\_MEDIA\_COMMENT
- DCMD\_MEDIA\_COMPOSER
- DCMD\_MEDIA\_DURATION
- DCMD\_MEDIA\_GENRE
- DCMD\_MEDIA\_NAME
- DCMD\_MEDIA\_PUBLISHER
- DCMD\_MEDIA\_RELEASE\_DATE
- DCMD\_MEDIA\_SONG
- DCMD\_MEDIA\_TRACK\_NUM
- DCMD\_MEDIA\_URL

Metadata retrieval messages to can be issued to:

- the MediaFS **control** file
- files entries in the MediaFS **playback** directory
- the **current** symbolic link
- any file not in the **.FS\_info.** directory

### Behavior of metadata requests

Metadata retrieved by a call to *devctl()* with a DCMD\_MEDIA\_\* metadata retrieval message is returned as a NULL-terminated string.

#### Return

If the queried media device does no support the requested metadata query, the *devctl()* call with the DCMD\_MEDIA\_\* metadata query message returns ENOTSUP.

#### Metadata for the currently playing file

To request metadata for the currently playing media file, use a metadata retrieval message with a call to the MediaFS **control** file, or to the **current** symbolic link.

Successful completion of a *devctl()* call with a metadata retrieval device control message to the **control** file or to the **current** symbolic link retrieves the requested metadata for the *currently playing* file.

**Metadata for a specified file**

To request metadata for a specific media file, use a metadata retrieval message with a call to that file.

Successful completion of a *devctl()* call with a metadata retrieval device control message to a file that is *not* the MediaFS **control** file or the **current** symbolic link retrieves the requested metadata for the *specified* file.

**DCMD\_MEDIA\_ALBUM**

DCMD\_MEDIA\_ALBUM queries a file for its album metadata, which the call returns in a NULL-terminated string. An empty string is valid if the album metadata is not known.

Buffer: **char[1]**

**DCMD\_MEDIA\_ARTIST**

DCMD\_MEDIA\_ARTIST queries a file for its artist metadata, which the call returns in a NULL-terminated string. An empty string is valid if the artist metadata is not known.

Buffer: **char[1]**

**DCMD\_MEDIA\_COMMENT**

DCMD\_MEDIA\_COMMENT queries a file for its comment metadata, which the call returns in a NULL-terminated string. An empty string is valid if there is no track comment metadata.

Buffer: **char[1]**

**DCMD\_MEDIA\_COMPOSER**

DCMD\_MEDIA\_COMPOSER

DCMD\_MEDIA\_COMPOSER queries a file for its composer metadata, which the call returns in a NULL-terminated string. An empty string is valid if the composer metadata is not known.

Buffer: **char[1]**

**DCMD\_MEDIA\_DURATION**

DCMD\_MEDIA\_DURATION

DCMD\_MEDIA\_DURATION queries a file for its duration, which the call returns as an unsigned integer indicating the track duration, in seconds.

Buffer: **char[1]**

**DCMD\_MEDIA\_GENRE**

DCMD\_MEDIA\_GENRE queries a file for its genre metadata, which the call returns in a NULL-terminated string. An empty string is valid if the genre metadata is not known.

Buffer: **char[1]**

### **DCMD\_MEDIA\_NAME**

DCMD\_MEDIA\_NAME queries a file for its name, which the call returns in a NULL-terminated string. An empty string is valid if the name is not known.

Buffer: **char[1]**

### **DCMD\_MEDIA\_PUBLISHER**

DCMD\_MEDIA\_PUBLISHER queries a file for its publisher metadata, which the call returns in a NULL-terminated string. An empty string is valid if the track number is not known.

Buffer: **char[1]**

### **DCMD\_MEDIA\_RELEASE\_DATE**

DCMD\_MEDIA\_RELEASE\_DATE queries a file for its release data metadata, which the call returns in the **\_media\_date** data structure.

Buffer: **char[1]**

### **DCMD\_MEDIA\_SONG**

DCMD\_MEDIA\_SONG queries a file for the song title, which the call returns in a NULL-terminated string.

Buffer: **char[1]**

### **DCMD\_MEDIA\_TRACK\_NUM**

DCMD\_MEDIA\_TRACK\_NUM queries a file for its track number, which the call returns in a NULL-terminated string. An empty string is valid if the track number is not known.

Buffer: **char[1]**

### **DCMD\_MEDIA\_URL**

DCMD\_MEDIA\_URL gets the URL for a media file.

Buffer: **char[1]**

**Playback Structures and Constants**

***In this chapter...***

Playback structures	59
Playback constants	64
iPod structures	67

This chapter describes MediaFS structures and constants used for playback monitoring and control:

- Playback structures
- Playback constants
- iPod structures

## Playback structures

MediaFS uses the following data structures to report and control playback information of files in the MediaFS framework:

- `_media_date`
- `_media_play`
- `_media_playback`
- `_media_playback_status`
- `_media_settings`
- `_media_speed`
- `_media_stream_info`

### `_media_date`

```
struct _media_date {
    uint16_t year;
    uint8_t  second;
    uint8_t  minutes;
    uint8_t  hours;
    uint8_t  day;
    uint8_t  month;
    uint8_t  weekday;
    char     text[40];
}
```

The `_media_date` structure contains track date information. It is populated and returned by `devctl()` when this function successfully issues a `DCMD_MEDIA_RELEASE_DATE` message to a MediaFS file.

Member	Type	Description
<i>year</i>	<code>uint16_t</code>	The release date year (0000-9999).
<i>second</i>	<code>uint8_t</code>	The release date second (00-59).

*continued...*

Member	Type	Description
<i>minutes</i>	<code>uint8_t</code>	The release date minute (00-59).
<i>hours</i>	<code>uint8_t</code>	The release date hour (00-59).
<i>day</i>	<code>uint8_t</code>	The release date day (01-31).
<i>month</i>	<code>uint8_t</code>	The release date month (01-12).
<i>weekday</i>	<code>uint8_t</code>	The release date day of the week (0-6), starting with 0 for Sunday and going to 6 for Saturday.
<i>text</i>	<code>char</code>	A free-form, NULL text field for date information for use with devices that cannot store date specifics. Maximum length is 39 characters. If this field is used, all other fields in this structure must be set to 0 (zero).

## `_media_play`

```
struct _media_play {
    unsigned pos;
};
```

The `_media_play` structure is used in combination with the `DCMD_MEDIA_PLAY_AT` command to set the starting play position. It includes at least the members described in the table below.

Member	Type	Description
<i>pos</i>	<code>unsigned</code>	The offset from time zero, in seconds, at which to start playback.

## `_media_playback`

```
struct _media_playback {
    uint32_t count;
    uint32_t index;
    uint8_t state;
    uint8_t flags;
    uint16_t metaseq;
    uint32_t length;
    uint32_t elapsed;
    uint32_t speed
};
```

The `_media_playback` structure has been deprecated and replaced by `_media_playback_status`.

## media\_playback\_status

```

struct _media_playback_status {
    uint32_t  flags;
    uint32_t  state;
    uint32_t  speed;
    uint32_t  trkidx_total;
    uint32_t  trkidx_current;
    uint32_t  trkpos_total;
    uint32_t  trkpos_current;
    uint32_t  chpidx_total;
    uint32_t  chpidx_current;
    uint32_t  chppos_total;
    uint32_t  chppos_start;
    uint32_t  metaseq;
    uint32_t  reserved[4];
};

```

The `_media_playback_status` structure contains information about the current playback state of the device. It is returned when a `DCMD_MEDIA_PLAYBACK` message is sent to the control file. Any change to any element in this structure must trigger a notification event on the MediaFS control file. The `_media_playback_status` structure includes at least the members described in the table below.

For more information about possible values for playback states and flags values, see “Media playback constants” below.

Member	Type	Description
<i>flags</i>	<code>uint32_t</code>	Flags to indicate the playback speed status as well as other information about a media file. See “The <i>flags</i> and <i>speed</i> members” and “Media playback constants” below.
<i>state</i>	<code>uint32_t</code>	The current playback state of the device. Must be one of <code>PLAYBACK_STATE_STOP</code> , <code>PLAYBACK_STATE_PLAY</code> or <code>PLAYBACK_STATE_PAUSE</code> . This value must be updated on a device playback state change. See “Media playback constants” below.
<i>speed</i>	<code>uint32_t</code>	The playback speed. This value is valid only if the <code>PLAYBACK_FLAG_FASTFWD</code> or the <code>PLAYBACK_FLAG_Fastrwd</code> flag is set. See “The <i>flags</i> and <i>speed</i> members” below.
<i>trkidx_total</i>	<code>uint32_t</code>	The total number of tracks in the playback list.
<i>trkidx_current</i>	<code>uint32_t</code>	The index reference for the currently playing track.

*continued...*

Member	Type	Description
<i>trkpos_total</i>	<code>uint32_t</code>	The length of the currently playing track, in milliseconds. Set to 0 if the track length is not known.
<i>trkpos_current</i>	<code>uint32_t</code>	The current position in the currently playing track, in milliseconds.
<i>chpidx_total</i>	<code>uint32_t</code>	The total number of chapters in the current media item. Set to 0 (zero) if there are no chapters.
<i>chpidx_current</i>	<code>uint32_t</code>	The index reference for the currently playing chapter.
<i>chppos_total</i>	<code>uint32_t</code>	The length of the currently playing chapter, in milliseconds. Set to 0 (zero) if the chapter length is not known.
<i>chppos_start</i>	<code>uint32_t</code>	The offset, in milliseconds, from the start of the chapter from which to start playback of the chapter. Set to 0 (zero) if this offset is not known.
<i>metaseq</i>	<code>uint32_t</code>	A sequence number that changes if metadata values have changed during playback of the current track.
<i>reserved</i> [4]	<code>uint32_t</code>	Reserved for future use.

### The *flags* and *speed* members

The value of the *flags* member can be a combination of:

- 0 (zero)
- `PLAYBACK_FLAG_FASTFWD` (0x01)
- `PLAYBACK_FLAG_FASTRWD` (0x02)
- `PLAYBACK_FLAG_SPEED_EXACT` (0x04)
- `PLAYBACK_FLAG_EVENTS` (0x08)
- `PLAYBACK_FLAG_ALBART` (0x10)
- `PLAYBACK_FLAG_IS_VIDEO` (0x20)

The `PLAYBACK_FLAG_FASTFWD` and `PLAYBACK_FLAG_FASTRWD` flag values are exclusive. If you set one, you must not set the other.

If *flags* is non-zero and the media device supports an indication of the exact playback speed, then `PLAYBACK_FLAG_SPEED_EXACT` flag can be set.

The *speed* member is updated on a playback speed change: 0 means paused, and 1 (one) means normal playback speed. The value of *speed* is only valid if the `PLAYBACK_FLAG_SPEED_EXACT` flag is set. If the

PLAYBACK\_FLAG\_SPEED\_EXACT flag is not set in the *flags* member, *speed* should be set to 0 (zero).

You should combine the PLAYBACK\_FLAG\_\* values to set the *flags* member.

See also “Media playback constants” below.

## **media\_settings**

```
struct _media_settings {
    uint8_t value
};
```

The `_media_setting` structure is used in conjunction with the DCMD\_MEDIA\_GET\_SHUFFLE, DCMD\_MEDIA\_SET\_SHUFFLE, DCMD\_MEDIA\_GET\_REPEAT and DCMD\_MEDIA\_SET\_REPEAT device control messages. It contains the repeat or random mode setting for the device, and includes at least the members described in the table below.

Member	Type	Description
<i>value</i>	uint8_t	The repeat or random mode value for the device.

Separate messages must be issued for getting and setting random and repeat modes; that is, it is *not* possible to get or set both the random and the repeat mode with one *devctl()* call. See also “Repeat and random mode setting constants” below.

## **media\_speed**

```
struct _media_speed {
    unsigned rate;
};
```

The `_media_speed` structure is used to set the current playback speed of the media device. The *rate* is a multiplication factor, where 1 (one) is normal playback speed. Valid values are 1, 2, 4, 8, 16 and 32.

This structure is used in conjunction with the DCMD\_MEDIA\_FASTFWD and DCMD\_MEDIA\_Fastrwd commands. It includes at least the members described in the table below.

Member	Type	Description
<i>rate</i>	unsigned	The playback speed multiplication factor; 1 (one) is normal speed.

## **media\_stream\_info**

```
struct _media_stream_info {
    unsigned char is_DRM;
    unsigned char seek_supported;
    unsigned char unused[2];
};
```

```

        uint32_t    reserved;
        uint64_t    stream_length;
};
    
```

The `_media_stream_info` structure is used to carry information that affects how a media stream can be played. It includes at least the members described in the table below:

Member	Type	Description
<i>is_DRM</i>	<b>char</b>	Indicate if the media stream is DRM (Digital Rights Management) protected. Set to either <b>Y</b> (protected) or <b>N</b> (not protected).
<i>seek_supported</i>	<b>char</b>	Indicate if the media stream supports seek capabilities. Set to either <b>Y</b> (supported) or <b>N</b> (not supported).
<i>unused</i> [2]	<b>char</b>	Reserved for future use.
<i>reserved</i>	<b>uint32_t</b>	Reserved for future use.
<i>stream_length</i>	<b>uint64_t</b>	The length of the media stream, in bytes. Set to <code>MEDIA_STREAM_LENGTH_UNKNOWN</code> if the media stream length is not known.

## Playback constants

The tables below list the constants defined in `dcmd_media.h` for playback monitoring and control.

### Media playback constants

The `PLAYBACK_FLAG_*` and `PLAYBACK_STATE_*` constants are defined in the structure `_media_playback_status`; they set or describe playback states.

Constant	Value	Description
<code>PLAYBACK_FLAG_FASTFWD</code>	0x01	Playback is in fast forward mode; the <code>DCMD_MEDIA_FASTFWD</code> control message has been applied, and playback speed is set to a number other than 1 (one).

*continued...*

Constant	Value	Description
PLAYBACK_FLAG_Fastrwd	0x02	Playback is in fast rewind mode; the DCMD_MEDIA_Fastrwd control message has been applied, and playback speed is set to a number other than 1 (one).
PLAYBACK_FLAG_Speed_Exact	0x04	The playback speed is the exact device speed; otherwise the playback speed is the value set with a DCMD_MEDIA_Fast*wd control message.
PLAYBACK_FLAG_Events	0x08	Events are waiting to be retrieved from the event queue.
PLAYBACK_FLAG_Albart	0x10	Album art is available to be read by a call with the DCMD_MEDIA_Albart_Read control message.
PLAYBACK_FLAG_Is_Video	0x20	Video is currently playing.
PLAYBACK_STATE_Stop	0	Playback is stopped.
PLAYBACK_STATE_Play	1	Playback is underway (not paused or stopped).
PLAYBACK_STATE_Pause	2	Playback is paused.

## Repeat and random mode setting constants

The REPEAT\_\* and SHUFFLE\_\* constants set or describe playback repeat and random mode settings. The REPEAT\_\* values should be used with the DCMD\_MEDIA\*\_REPEAT messages, and the SHUFFLE\_\* should be used with the DCMD\_MEDIA\*\_SHUFFLE messages.

Constant	Value	Description
REPEAT_OFF	0	Repeat mode is off.
REPEAT_ONE_TRACK	1	Repeat the current track only.
REPEAT_ALL_TRACKS	2	Repeat all tracks.
REPEAT_FOLDER	3	Repeat all tracks in the folder.
REPEAT_SUBFOLDER	4	Repeat all tracks in the subfolder.
SHUFFLE_OFF	0	Random mode is off.

*continued...*

Constant	Value	Description
SHUFFLE_TRACKS	1	Play all tracks in pseudo-random order.
SHUFFLE_ALBUMS	2	Play all albums in pseudo-random order. The playback order of the tracks depends on whether SHUFFLE_TRACKS is set.
SHUFFLE_FOLDER	3	Play all tracks in the folder in pseudo-random order.
SHUFFLE_SUBFOLDER	4	Play all tracks in the subfolder in pseudo-random order.

## Media stream constants

The MEDIA\_STREAM\_\* constants set or describe media streams.

Constant	Value	Description
MEDIA_STREAM_LENGTH_UNKNOWN	-1	The media stream length is not known.

## Media type strings

The table below lists common media type strings used in the `info.xml` file's `<media>/<type>` element to describe the mediastore. These mediastore types are consistent with the mediastore types defined by the MME's MME\_STORAGETYPE\_\* constants in order to map type to string.

Constant	Value	Description
MEDIA_TYPE_UNKNOWN	"UNKNOWN"	Unknown storage type
MEDIA_TYPE_AUDIOCD	"AUDIOCD"	Audio CD
MEDIA_TYPE_VCD	"VCD"	Video CD
MEDIA_TYPE_SVCD	"SVCD"	Super Video CD
MEDIA_TYPE_FS	"FS"	RAM disc
MEDIA_TYPE_DVDAUDIO	"DVDAUDIO"	Audio DVD
MEDIA_TYPE_DVDVIDEO	"DVDVIDEO"	Video DVD
MEDIA_TYPE_IPOD	"IPOD"	iPod device
MEDIA_TYPE_KODAKCD	"KODAKCD"	Kodak picture CD

*continued...*

Constant	Value	Description
MEDIA_TYPE_PICTURECD	“PICTURECD”	Other picture CD
MEDIA_TYPE_A2DP	“A2DP”	A2DP protocol for Bluetooth
MEDIA_TYPE_SMB	“SMB”	MEDIA_TYPE_FS
MEDIA_TYPE_FTP	“FTP”	Internet FTP connection
MEDIA_TYPE_HTTP	“HTTP”	Internet HTTP connection
MEDIA_TYPE_NAVIGATION	“NAVIGATION”	Navigation CD or DVD.
MEDIA_TYPE_PLAYSFORSURE	“PFS”	PlaysForSure and similar devices.
MEDIA_TYPE_UPNP	“UPNP”	Devices using UPnP protocol.

## iPod structures

MediaFS uses the following data structures to manage iPod devices:

- `_media_ipod_daudio`

### `_media_ipod_daudio`

```
struct _media_ipod_daudio {
    unsigned rate;
    int      sndchk;
    int      voladj;
    unsigned reserved;
};
```

The `_media_ipod_daudio` structure is used to carry information about an iPod’s capabilities, and instructions to be applied to the iPod. It includes at least the following members:

Member	Type	Description
<i>rate</i>	<b>unsigned</b>	The sample rate, in Hertz, for the media on the device. Standard values are 32000, 44100 and 48000; some devices also support 8000, 11025, 12000, 16000, 22050 or 24000 Hertz.
<i>sndchk</i>	<b>int</b>	The device sound check value, as gain in decibels plus or minus. If the sound check capability is disabled on the device, this value must be set to 0.
<i>voladj</i>	<b>int</b>	The device volume adjustment, a gain in decibels plus or minus.

*continued...*

---

<b>Member</b>	<b>Type</b>	<b>Description</b>
<i>reserved</i>	<b>unsigned</b>	Reserved for future use.

---

### *In this chapter...*

How to retrieve album art	71
Album art messages	71
Album art structures	73
Album art constants	74

MediaFS supports retrieval of album art associated with media files, if this capability is supported by the media device:

- How to retrieve album art
- Album art messages
- Album art structures
- Album art constants

## How to retrieve album art

To retrieve album art associated with a media file, a high-level multimedia application, such as the MME, and the device driver must perform the following steps in sequence:

- 1 Client application:** Issue a `DCMD_MEDIA_ALBART_INFO` message to the MediaFS `control` file, or to another specified file to find out if there is artwork associated with the file.  
**Device controller:** Retrieve the required information from the device and return it in the `_media_albart_entry` data structure. If artwork is available, set the appropriate values in this structure's *flag* and *pos* members.
- 2 Client application:** If artwork is available, issue a `DCMD_MEDIA_ALBART_LOAD` message.  
**Device controller:** Complete and return the `_media_albart_entry` structure with the image description, so that the client application can know the size of the image and prepare to read it.
- 3 Client application:** Issue `DCMD_MEDIA_ALBART_READ` messages to read the artwork and place it in a buffer, managing the returned image blocks and using them to reconstruct the image after the complete image has been read.  
**Device controller:** Retrieve as requested the artwork in blocks from the media device, returning to the client application, as appropriate, one of:
  - the number of bytes sent, if part of the image data was sent
  - `EAGAIN`, if the device is still in the process of sending the image block and the client application needs to try again to get the next image block
  - `ENODATA`, if the entire image has been read and there is no more data to send

## Album art messages

To support album art retrieval, a device controller must support the following control messages from a higher-level application:

- `DCMD_MEDIA_ALBART_INFO`
- `DCMD_MEDIA_ALBART_LOAD`

- DCMD\_MEDIA\_ALBART\_READ

---

If the queried media device does not support the album art retrieval, the *devctl()* call with the DCMD\_MEDIA\_ALBART\_\* message returns ENOTSUP.

---

### DCMD\_MEDIA\_ALBART\_INFO

The DCMD\_MEDIA\_ALBART\_INFO message is used to query a media file for the presence of album artwork. The album art information for the file is placed in the `_media_albart_entry` data structure.

On success, a call to *devctl()* with this message returns EOK; the *devctl()* *dev\_info\_ptr* parameter points to the number or entries in the array with the album artwork.

Buffer: `_media_albart_entry`

### DCMD\_MEDIA\_ALBART\_LOAD

The DCMD\_MEDIA\_ALBART\_LOAD message is used to retrieve the index information for a file whose album artwork is to be retrieved. The requested information is placed in the `_media_albart_entry` data structure.

On success, a call to *devctl()* with this message returns EOK; the *devctl()* *dev\_info\_ptr* parameter points to the index for the specified file.

Buffer: `_media_albart_entry`

### DCMD\_MEDIA\_ALBART\_READ

The DCMD\_MEDIA\_ALBART\_READ message is used to read an album artwork image. The read process starts with the *devctl()* call with the DCMD\_MEDIA\_ALBART\_READ message and ends when the entire image has been read.

Image data is read only once and returned; once a portion of an image has been read and returned, it is not returned again. The device controller must manage reading data blocks from the device, and the calling application must manage the returned data blocks until the entire image has read and can be passed up to an HMI application for display.

The total size of the image, in bytes, and other image information is placed in the `_media_img_desc` data structure.

When a call to *devctl()* with the DCMD\_MEDIA\_ALBART\_READ message completes the device controller must return one of:

- ENODATA — the entire image has been read
- EAGAIN — the image is still being received

In addition, on completion of a successful call the *dev\_info\_ptr* parameter must point to the number of bytes received.

Buffer: `_media_albart`

## Album art structures

MediaFS uses the following data structures to process the album art for media files:

- `_media_albart`
- `_media_albart_entry`
- `_media_img_desc`

### `_media_albart`

```
struct _media_albart {
    uint32_t          flags;
    uint32_t          pos;
    uint32_t          reserved[6];
    struct _media_img_desc desc;
    uint8_t          data[1];
};
```

The `_media_albart` structure contains the album art data retrieved from a media file. It is populated and returned by `devctl()` when it successfully issues a `DCMD_MEDIA_ALBART_READ` message to a MediaFS file.

The data in this structure may not be the complete requested image, and multiple reads may be required to read a complete image. See `DCMD_MEDIA_ALBART_READ` in the chapter MediaFS Messages.

Member	Type	Description
<i>flags</i>	<code>uint32_t</code>	Flags specifying how to interpret position information for the album art. See the descriptions of the <code>ALBART_FLAG_POS_*</code> constants under “Album art constants” below.
<i>pos</i>	<code>uint32_t</code>	Position at which to display the album art. This position is either the offset, in milliseconds, in the track if <code>ALBART_FLAG_POS_TRKPOS</code> is set; or the chapter, if <code>ALBART_FLAG_POS_CHPIDX</code> is set.
<i>reserved</i> [6]	<code>uint32_t</code>	Reserved for future use.
<i>desc</i>	<code>struct</code>	The <code>_media_img_desc</code> structure with the image description.
<i>data</i> [1]	<code>uint8_t</code>	An array for the album art data.

### `_media_albart_entry`

```
struct _media_albart_entry {
    uint16_t          index;
    uint16_t          reserved[3];
    uint32_t          flags;
    uint32_t          pos;
};
```

```

    struct _media_img_desc desc;
};

```

Member	Type	Description
<i>index</i>	<code>uint16_t</code>	The index to match for this album art entry.
<i>reserved</i> [3]	<code>uint16_t</code>	Reserved for future use.
<i>flags</i>	<code>uint32_t</code>	Flags specifying how to interpret position information for the album art. See the descriptions of the <code>ALBART_FLAG_POS_*</code> constants under “Album art constants” below.
<i>pos</i>	<code>uint32_t</code>	Position at which to display the album art. This position is either the offset, in milliseconds, in the track if <code>ALBART_FLAG_POS_TRKPOS</code> is set; or the chapter, if <code>ALBART_FLAG_POS_CHPIDX</code> is set.
<i>desc</i>	<code>struct</code>	The <code>_media_img_desc</code> structure with the image description.

## `_media_img_desc`

```

struct _media_img_desc {
    uint32_t width;
    uint32_t height;
    uint32_t size;
    uint32_t reserved;
    char     mimetype[64];
};

```

Member	Type	Description
<i>width</i>	<code>uint32_t</code>	The album art image width, in pixels.
<i>height</i>	<code>uint32_t</code>	The album art image height, in pixels.
<i>size</i>	<code>uint32_t</code>	The album art image size, in bytes.
<i>reserved</i>	<code>uint32_t</code>	Reserved for future use.
<i>mimetype</i> [64]	<code>char</code>	A string with the album art MIME type.

## Album art constants

The table below lists the constants defined in `dcmd_media.h` for album artwork processing.

Constant	Value	Description
ALBART_FLAG_POS_NONE	0x00000000	No position information is available.
ALBART_FLAG_POS_TRKPOS	0x00000001	The position is expressed in milliseconds from the start of the track.
ALBART_FLAG_POS_CHPIDX	0x00000002	The position is the chapter number.
ALBART_FLAG_POS_MASK	0x0000000F	A mask for stripping out bits not relevant to the <i>flags</i> member of the <code>_media_img_desc</code> data structure.
ALBART_INDEX_NONE	0xFFFF	Indicate that no specific index is used, so that a call to <code>devctl()</code> with the <code>DCMD_MEDIA_ALBART_LOAD</code> message attempts to load the best match rather than a specific file.

***In this chapter...***

Working with MediaFS events	79
Event types	81
MediaFS events and their structures	81

This chapter describes MediaFS events and the data structures they use.

- Working with MediaFS events
- MediaFS event types
- MediaFS events and their structures

## Working with MediaFS events

MediaFS supports events for communication between devices and upper-level applications. A device driver should, therefore, be designed to write, whenever the underlying device changes state, the appropriate MediaFS events and their payloads to the MediaFS event queue so that they can be read by client applications.

This section presents:

- The MediaFS event queue
- Reading MediaFS events

For a complete list of supported MediaFS event types, events and event data structures, see “MediaFS events and their structures” below.

### The MediaFS event queue

The MediaFS event queue is the means by which a device driver can communicate playback status changes and updates, and device state changes to client applications in the sequence in which they occur.

The MediaFS event queue:

- is a fixed-size, circular queue
- implements FIFO (first in, first out) behavior

The MediaFS queue’s FIFO behavior means that a client reading items from the queue will always receive events in chronological order.

### Writing events to the queue

When the device controller writes an event to the MediaFS queue, it must:

- Set to `PLAYBACK_FLAG_EVENTS` the *flags* member of the `_media_playback_status` structure.
- Send an asynchronous notification to all clients registered on the `control` file.

### Event queue management

The device controller should ensure the following event queue behavior:

- If the event queue is full when the device driver writes an event to it, the new event should overwrite the oldest event in the queue.

- When all items in the queue have been removed, the device controller should clear the `PLAYBACK_FLAG_EVENTS` flag in the `_media_playback_status` data structure's `flags` member.

---

In order to assure backwards compatibility with MediaFS 1.0, which did not support events, the MediaFS event queue is optional.

---

## Reading MediaFS events

Multimedia applications using MediaFS should be designed to use `devctl()` calls with the `DCMD_MEDIA_READ_EVENTS` to read events from the MediaFS event queue, and to use the information provided by these events to manage media playback and other activities. To read MediaFS events, an application must call the `devctl()` function with the `DCMD_MEDIA_READ_EVENTS` message.

### DCMD\_MEDIA\_READ\_EVENTS

`DCMD_MEDIA_READ_EVENTS` instructs MediaFS to populate the client application's data buffer with data from the MediaFS event queue.

Buffer: `char[1]`

### Managing your buffer when using DCMD\_MEDIA\_READ\_EVENTS

The `DCMD_MEDIA_READ_EVENTS` is used to instruct MediaFS to populate the client application's data buffer with data from the MediaFS event queue. *It is the responsibility of the client application to ensure that it has a buffer large enough for the events in the MediaFS event queue.*

#### Behavior when the queue is larger than the client application buffer

If the number of bytes of data in the event queue is *greater than* the size of the client application's data buffer, a call to `devctl()` with the `DCMD_MEDIA_READ_EVENTS` message will:

- *not* write any data to the client application's data buffer
- set the `_media_event` structure's `len` member to the number of bytes *required* in the data buffer
- return EOK

In this case, the client application should:

- 1 Increase the size of the buffer it uses for the MediaFS events to at least the size returned in `len`.
- 2 Call `devctl()` with the `DCMD_MEDIA_READ_EVENTS` message again to read the events from the queue.

**Behavior when the queue is smaller than or equal to the client application buffer**

If the number of bytes of data in the event queue is *less than or equal* to the size of the client application's data buffer, a call to *devctl()* with the DCMD\_MEDIA\_READ\_EVENTS message will:

- fill the buffer
- set the `_media_event` structure's *len* member to the number of bytes of data in the buffer to the number of bytes of data in the data buffer

## Event types

MediaFS uses five types of events. Values for these event types are carried in the `_media_event` structure's *type* member. They are described in the table below:

Event type	Value	Description
MEDIA_EVENT_ERROR	0	Error
MEDIA_EVENT_WARNING	1	Warning
MEDIA_EVENT_TRACK	2	Communicate a track information change.
MEDIA_EVENT_TIME	3	Communicate a time update.
MEDIA_EVENT_METADATA	4	Communicate changes to metadata.

## MediaFS events and their structures

This section describes MediaFS events, organized by event type. It includes:

- The `_media_event` data structure
- Track, time and other information update events
- Metadata update events
- Error and warning events

### The `_media_event` data structure

```
_media_event
struct _media_event {
    uint32_t type;
    uint32_t len;
};
```

The `_media_event` structure is included in all other MediaFS event structures. It specifies the event type, and the length of the event data. This structure includes at least the members described in the table below.

Member	Type	Description
<i>type</i>	<code>uint32_t</code>	The event type; see “Event types” above.
<i>len</i>	<code>uint32_t</code>	The length of the event data, in bytes (including padding to 8-byte alignment).

## Track, time and other information update events

MediaFS information events signal an update to track or time information for the specified media track or file. Depending on the type of information they communicate, these events carry either the `_media_event_info`, the `_media_event_time` or the `_media_event_track` data structure.

The table below describes the MediaFS track and time update events:

Event	Value	Description
<code>MEDIA_EVENT_INFO_UNKNOWN</code>	0	Events carrying information, such as time or track updates, about a track or media file.

### `_media_event_info`

```

struct _media_event_info {
    struct _media_event event;
    uint32_t             index;
    uint32_t             type;
    char                 value[1];
};

```

The `_media_event_info` structure contains track or media file information. It should be populated when track or media file information changes, and, if relevant, included with the information events that MediaFS places in its event queue.

Member	Type	Description
<i>event</i>	<code>struct</code>	The <code>_media_event</code> structure with the event type and size.
<i>index</i>	<code>uint32_t</code>	The index number for the track to which the event is associated.
<i>type</i>	<code>uint32_t</code>	The type of information event; see “Track, time and other information update events” above.
<i>value [1]</i>	<code>char</code>	A character string with the changed track information.

**`_media_event_time`**

```

struct _media_event_time {
    struct _media_event event;
    uint32_t          index;
    uint32_t          elapsed;
    uint32_t          duration;
};

```

The `_media_event_time` structure contains track or media file time information. It should be populated when track or media file time information changes, and, if relevant, included with the information events that MediaFS places in its event queue.

Member	Type	Description
<i>event</i>	<b>struct</b>	The <code>_media_event</code> structure with the event type and size.
<i>index</i>	<b>uint32_t</b>	The index number for the track to which the event is associated.
<i>elapsed</i>	<b>uint32_t</b>	The elapsed time for the current track, in milliseconds.
<i>duration</i>	<b>uint32_t</b>	The track duration (total time) of the current track, in milliseconds.

**`_media_event_track`**

```

struct _media_event_track {
    struct _media_event event;
    uint32_t          index;
    uint32_t          duration;
    char              trackpath[1];
};

```

The `_media_event_track` structure contains track or media file information. It should be populated when track or media file information changes, and, if relevant, included with the information events that MediaFS places in its event queue.

Member	Type	Description
<i>event</i>	<b>struct</b>	The <code>_media_event</code> structure with the event type and size.
<i>duration</i>	<b>uint32_t</b>	The track duration (total time) of the current track, in milliseconds.
<i>trackpath</i>	<b>char</b>	A character string with the path (relative to the mountpoint) of the current media file or track.

## Metadata update events

MediaFS metadata events signal an update or other change to metadata for the specified media track or file. These events carry the data structure `_media_event_metadata`.

The table below describes the MediaFS metadata update events:

Event	Value	Description
MEDIA_EVENT_METADATA_UNKNOWN	0	An unspecified change has been made to the file's metadata.
MEDIA_EVENT_METADATA_SONG	1	Change to the file's song metadata.
MEDIA_EVENT_METADATA_ALBUM	2	Change to the file's album metadata.
MEDIA_EVENT_METADATA_ARTIST	3	Change to the file's artist metadata.
MEDIA_EVENT_METADATA_GENRE	4	Change to the file's genre metadata.
MEDIA_EVENT_METADATA_COMPOSER	5	Change to the file's composer metadata.
MEDIA_EVENT_METADATA_RELEASE_DATE	6	Change to the file's release date metadata.
MEDIA_EVENT_METADATA_TRACK_NUM	7	Change to the file's track number metadata.
MEDIA_EVENT_METADATA_PUBLISHER	8	Change to the file's publisher metadata.
MEDIA_EVENT_METADATA_DURATION	9	Change to the file's duration metadata.
MEDIA_EVENT_METADATA_NAME	10	Change to the file's name metadata.
MEDIA_EVENT_METADATA_COMMENT	11	Change to the file's comment metadata.

**`_media_event_metadata`**

```

struct _media_event_metadata {
    struct _media_event event;
    uint32_t          type;
    uint32_t          index;
    uint32_t          duration;
    struct _media_date date;
    char              value[1];
};

```

The `_media_event_metadata` structure contains track metadata. It should be populated whenever metadata for a track or media file changes, and included with the metadata update events that MediaFS places in its event queue.

Member	Type	Description
<i>event</i>	<b>struct</b>	The <code>_media_event</code> structure with the event type and size.
<i>type</i>	<b>uint32_t</b>	The type of metadata event; see “Metadata update events” above.
<i>index</i>	<b>uint32_t</b>	The index number for the track to which the event is associated.
<i>duration</i>	<b>uint32_t</b>	The track date.
<i>date</i>	<b>struct</b>	The <code>_media_date</code> structure with the track date information.
<i>value</i> [1]	<b>char</b>	A UTF-8 encoded character string for character-based metadata types.

**Error and warning events**

MediaFS error and warning events signal an error or other condition that requires attention from the client application. These events carry, respectively, the data structure `_media_event_error` or `_media_event_warning`.

The table below describes the MediaFS error and warning events:

Event	Value	Description
<code>MEDIA_EVENT_ERROR_UNKNOWN</code>	0	An unspecified error condition has occurred.
<code>MEDIA_EVENT_ERROR_DRM</code>	1	A DRM error has occurred.
<code>MEDIA_EVENT_ERROR_CORRUPT</code>	2	The media file is corrupt.

*continued...*

Event	Value	Description
MEDIA_EVENT_WARNING_UNKNOWN	0	An unspecified condition that requires attention has occurred.

### `_media_event_error`

```
struct _media_event_error {
    struct _media_event event;
    uint32_t index;
    uint32_t type;
};
```

The `_media_event_error` structure contains track or media file error information. It should be populated when an error is encountered with a track or media file, and included with the error events that MediaFS places in its event queue.

Member	Type	Description
<i>event</i>	<code>struct</code>	The <code>_media_event</code> structure with the event type and size.
<i>index</i>	<code>uint32_t</code>	The index number for the track to which the event is associated.
<i>type</i>	<code>uint32_t</code>	The type of error event; see “Error and warning events” above.

### `_media_event_warning`

```
struct _media_event_warning {
    struct _media_event event;
    uint32_t index;
    uint32_t type;
};
```

The `_media_event_warning` structure contains track or media file error information. It should be populated when a warning situation is encountered with a track or media file, and included with the error events that MediaFS places in its event queue.

Member	Type	Description
<i>event</i>	<code>struct</code>	The <code>_media_event</code> structure with the event type and size.
<i>index</i>	<code>uint32_t</code>	The index number for the track to which the event is associated.

*continued...*

---

<b>Member</b>	<b>Type</b>	<b>Description</b>
<i>type</i>	<code>uint32_t</code>	The type of warning event; see “Error and warning events” above.

***In this appendix...***

MediaFS structure	91
<code>info.xml</code> file	91

This appendix presents some examples that help illustrate how to use MediaFS. It contains:

- MediaFS structure
- `info.xml` file

## MediaFS structure

The following presents a MediaFS instance representing an iPod device:

```

ipod0/:
total 3
dr-xr-xr-x  3 root    root    512 Jun 01 11:28 .
dr-xr-xr-x  2 root    root      0 Jun 01 11:28 ..
dr-xr-xr-t  3 root    root    512 Jun 01 11:28 .FS_info.
dr-xr-xr-x  2 root    root    512 Jun 01 11:28 Music

ipod0/.FS_info.:
total 6
dr-xr-xr-t  3 root    root    512 Jun 01 11:28 .
dr-xr-xr-x  3 root    root    512 Jun 01 11:28 ..
nrw-rw-rw-  1 root    root      0 Jun 01 11:28 control
lrwxrwxrwx  1 root    root      0 Jun 01 11:28 current ->
-r--r--r--  1 root    root   1127 Jun 01 11:28 info.xml
dr-xr-xr-x  2 root    root    512 Jun 01 11:28 playback

ipod0/.FS_info./playback:
total 2
dr-xr-xr-x  2 root    root    512 Jun 01 11:28 .
dr-xr-xr-t  3 root    root    512 Jun 01 11:28 ..

ipod0/Music:
total 10
dr-xr-xr-x 10 root    root    512 Jun 01 11:28 .
dr-xr-xr-x  3 root    root    512 Jun 01 11:28 ..
dr-xr-xr-x  2 root    root    512 Jun 01 11:28 Albums
dr-xr-xr-x  2 root    root    512 Jun 01 11:28 Artists
dr-xr-xr-x  2 root    root    512 Jun 01 11:28 Audiobooks
dr-xr-xr-x  2 root    root    512 Jun 01 11:28 Composers
dr-xr-xr-x  2 root    root    512 Jun 01 11:28 Genres
dr-xr-xr-x  2 root    root    512 Jun 01 11:28 Playlists
dr-xr-xr-x  2 root    root    512 Jun 01 11:28 Podcasts
dr-xr-xr-x  2 root    root    512 Jun 01 11:28 Songs

```

## info.xml file

The following presents an MediaFS `info.xml` file for an iPod device:

```

<?xml version="1.0" standalone="yes"?>
<info>

```

```

<media>
  <device>iPod</device>
  <protocol>
